

SEASON ONE

Points

No points have been issued. This page shows the activity a points programme would be computed from — your own traded volume, drawn from your closed-position history — so that when issuance does start, you can already see the inputs and check them yourself.

PROGRAMME

EPOCH

SOURCE /position

POINTS BALANCE

Not issued

No points service exists in this system. There is nothing to accrue into, so this is not a zero balance — it is the absence of a balance.

RANK

—

A leaderboard needs a scored population. Without issuance there is no score and no population.

EPOCH

—

No epoch length, start date or emission figure has been decided, so no countdown can be honest.

REFERRAL SHARE

—

Cut from scope. The landing mockup's 25% figure describes a programme that was never built.

WHY THIS PAGE HAS NO NUMBERS IN IT

READ THIS BEFORE ASSUMING ANYTHING

Points issuance is not live, and nothing on this page is an allocation.

Whitespace runs on Whitechain testnet 1874 with a faucet collateral token. There is no points contract, no emission schedule, no snapshot, and no commitment — explicit or implied — that trading today will be rewarded later.

- **No total, no rank, no epoch.** The four tiles above would each need a service that does not exist. They show what they show rather than a plausible-looking number.
- **The volume figures below are yours, not a score.** They are a straight sum over your own closed positions from the read API. They are not weighted, not multiplied, and not points.
- **Nothing here is a promised allocation.** If a programme is ever announced, its rules will be published before it starts — and they may not use any of these figures.
- **Testnet collateral has no value.** USDW is minted from an uncapped faucet, so volume denominated in it is a measure of activity, never of capital at risk.

NOTHING TO ACCRUE INTO

YOUR ACTIVITY

Every figure here is derived from GET /positions/address and GET /positions/address — the same as the same portfolio

[EMPTY]

No closed trades on this address

Traded volume is computed from fully-closed positions, and this address has none yet. [Open a position](#); once it closes it will appear here and in your portfolio.

Portfolio

Everything this address holds on Whitespace, in one place: USDW in the wallet, collateral locked in open positions, the LP vault position, and every trade already closed. Figures come from the read API and from direct contract reads — nothing on this page is estimated except where it says so.

ADDRESS0x00

COLLATERALUSDC

NETWORKWHITE

ACCOUNT VALUE

52.50USDW

Wallet + margin in positions + unrealised PnL + LP vault.

WALLET

52.50USDW

Free collateral, not committed to anything.

MARGIN IN POSITIONS

0.00USDW

0 open · 0.00 USDW notional. Isolated margin: a loss is capped at the collateral in that one position.

UNREALISED PNL

+0.00USDW

Estimate at the live mark. Spread, price impact, funding and rollover apply at settlement and are not included.

REALISED PNL

+0.00USDW

Across 0 fully-closed trades. Payout minus collateral, so every fee the contract charged is already in it.

LP VAULT

0.00USDW

0.00 shares of a 100,000 USDW LP

ACCOUNT VALUE

Each row is one read. The total is only shown when all four are non-zero.

Wallet (USDW)	52.50
Margin in open positions	0.00
Unrealised PnL (estimate)	+0.00
LP vault position	0.00
Account value	52.50 USDW

OPEN POSITIONS · 0

Marks refresh every 5s from GET /price/:pairIndex. Close a position from the terminal.

[EMPTY]

No open positions

This address holds no open position on any market. [Open one from the terminal](#) — remember the order is a request first: it fills, or it cancels and refunds, only once a keeper delivers a signed price report.

How Whitespace works

Whitespace is a perpetual-futures exchange on Whitechain testnet 1874. You trade against a shared liquidity vault at a price signed by an off-chain oracle — there is no order book and no counterparty to find. This page explains what that means for your money, including the parts that are awkward. Every figure marked in **bold** below is read live from the deployed contracts as you load the page.

CONTENTS

- 01 The model
- 02 Order lifecycle
- 03 Slippage & protection
- 04 Margin & liquidation
- 05 The signed oracle
- 06 Fees

- 08 What is not live

01

A vault, not an order book

On a normal exchange your counterparty is another trader, matched against you in a book. Here it is a **shared LP vault**. Depositors put USDW into the vault; the vault takes the other side of every position, and the price you open and close at comes from an oracle rather than from whoever happens to be quoting. When you win, the vault pays you. When you lose, the vault keeps your loss.

WHY THERE IS NO BOOK

A genuinely on-chain order book is not a matter of writing one. The only production example, Hyperliquid, needed a bespoke consensus protocol, a matching engine inside chain state, ~200,000 orders/sec, and a mempool that understands order-book semantics well enough to sort cancels ahead of aggressive orders. None of that is reachable as ordinary EVM contracts on a one-second-block chain with a public mempool — which is why even on Arbitrum, no perp team keeps the book on-chain.

The decisive argument is simpler than the technical one: **a book with no market makers is an empty screen**. This is an independent project with no market-making relationships, on a chain measured at 0.4 transactions per block. The vault model exists precisely because it produces tradeable liquidity with zero market makers — liquidity is bought with vault capital instead of negotiated with a desk.

WHAT THAT COSTS YOU, STATED PLAINLY

- **No price discovery.** The protocol is a price taker. It cannot disagree with its oracle, so oracle correctness is existential rather than merely important — see section 05.
- **Your size is bounded by the vault, not by demand.** Open-interest caps exist because the vault has to be able to pay everyone who is winning at once. An order that would breach the cap is cancelled with **EXPOSURE LIMITS**.
